Asset registry interview task

Design and implement assets registry service and api. Service ingests and persists data about crypto networks and assets supported by those networks. Data is used by other services to validate transactions (ie is the transaction to supported asset). As well as by front end to display a list of networks and associated assets, as well as display users portfolio.

- Ingest crypto networks and tokens (assets) data from [Coin Gecko API](#). Store data for efficient retrieval and access via API.
 - There is a rate limit on coin gecko api. Make sure to only make 30 coin gecko calls per minute.
- Setup docker container deployment.
- API should have following endpoint:
 - `/networks` returns list of supported networks
 - `/tokens?network\_id=` returns list of tokens for given network. (paged)
 - `/tokens?search=` return tokens matching the term (address, symbol, name etc)
 - `/tokens?wallet=0x` return only tokens that have non zero balances, given wallet address
- Front end
 - Production ready front end that displays list of networks and supported assets
 - User is able to enter wallets and see coins and balance for all coins in his wallet
- Preferred tech stack
 - React, Typescript, nodejs
 - PostgreSQL
 - Zod
 - Tailwind
 - shadcn

We are looking for production level implementation. Please leave notes if something is left out due to time constraints.

If anything is unclear:

- Make a reasonable assumption
- Document it in your README
- Explain your reasoning

Use of AI is allowed, but again we are expecting production level code that will be scrutinized.
